International B2B Shipping

International bulk shipping can be managed either as a website-level Table Rates matrix or as country prices on each product.

Table Rates by destination

Use this model when a forwarder supplies cart-level prices. Import `Bulkgood = 1` rows for each destination, region, postcode and condition threshold. Place **Table Rate** first in the source priority.

Separate rows are needed for countries that share the same commercial zone. Magento's Table Rates file does not accept a named zone in place of the country field.

Country prices on products

Use product country rows when each SKU has its own destination charge. A zero threshold creates one price for the country. Further rows can introduce weight, discounted item value or item-quantity tiers according to the active Table Rates condition.

Country-source coverage should be consistent. If one product has a destination row and another does not, the available country source can win without including the second product's general price.

Checklist for each market

- The website sells and ships the product.
- Product Bulkgood values are saved in the correct website scope.
- A `Bulkgood = 1` Table Rates row matches the destination.
- The configured currency and tax handling match the storefront's shipping presentation.
- Region and postcode wildcards are intentional.
- A destination without a valid rate produces the configured unavailable result.

Bulkgood does not calculate customs duties, import taxes, Incoterms or currency conversion. Handle those separately in the checkout and order process.
